

CHASSIS LOCKING BAR

ABSTRACT

The present invention is directed to an apparatus and method for allowing securing/unsecuring of an access panel from a generally opposing side of a chassis. The mechanism includes a latch for securing the panel disposed on a side of the chassis. A locking mechanism extends from the latch to a side opposite the latch. The locking mechanism provides a locking bar which may be manipulated to either positively secure the panel, via a screw or lock, or release the panel from the side opposite the latch.
